EX.NO:06 DASHBOARD – STUDENT MANAGEMENT SYSTEM

ROLL NO: 240701573

NAME: UMAR FAROOK K

AIM:

To design dashboards in Zoho Creator for the Student Management System that display key student statistics such as the number of enrolled students, gender-wise counts and course completion status.

THEORY:

A dashboard is a single screen that presents the most important information of an application in a summarised and visual form. Instead of opening several forms and reports and reading every record, the user can see the key figures at a glance and quickly understand the current state of the system.

Zoho Creator is a low-code platform that lets users build database-driven applications. The data entered through forms is stored in the application, and reports and dashboards read from that data. A dashboard is built by placing components on a page, such as number (KPI) cards, charts and reports. Each component is linked to a form, uses an aggregate function such as Count, and can be limited by a criteria so that it counts only the records that match a condition. Because dashboards read the stored records directly, the figures are updated automatically when records are added, edited or deleted.

The Student Management System in this experiment keeps its data in four modules: Student Profile, Course Enrollment, Guardian Contact and Academic Record. The Student dashboard section of the application contains three dashboards (Student dashboard, Dashboard1 and Dashboard2), which summarise the data of these modules for administrators and staff.

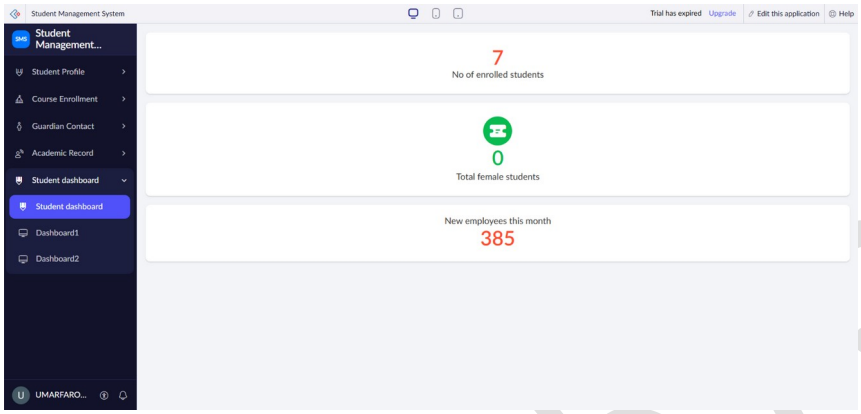

PROCEDURE:

1. Sign in to Zoho Creator and open the Student Management System application, which contains the forms Student Profile, Course Enrollment, Guardian Contact and Academic Record.
2. Add sample student records through the forms so that the dashboards have data to display.
3. Create a new dashboard named Student dashboard and add number (KPI) components for the count of enrolled students and the total female students.
4. Select the source form for each component, choose Count as the aggregate function, and apply a criteria where needed (for example, Gender equal to Female).
5. Create Dashboard1 and add a component that shows the Male Count by applying the criteria Gender equal to Male.
6. Create Dashboard2 and add two components titled Course Completion by Department, one showing the count of completed courses and one showing the incompleted courses.
7. Save the dashboards so that they appear in the Student dashboard section of the application menu.
8. Open the application, view each dashboard and verify that the figures match the records stored in the forms.

OUTPUT:

Output 1: Student dashboard

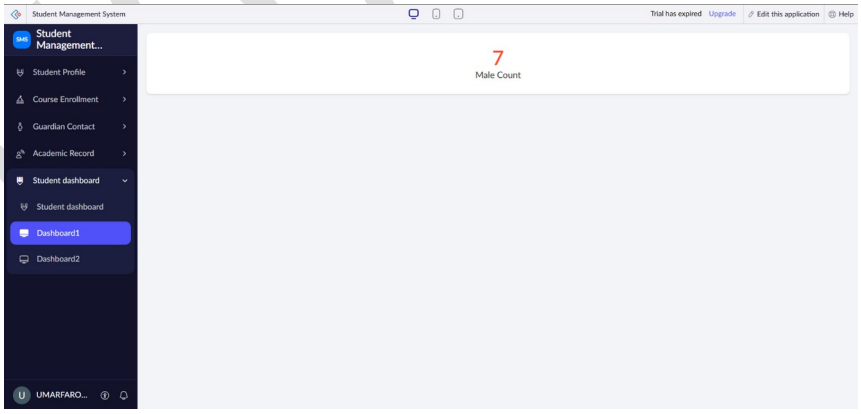

The Student dashboard is the main page of this section. It is built from summary cards, where each card shows one number calculated from the stored data. A card is linked to a form, uses the Count function and may apply a criteria, so the value it shows always reflects the latest records.

This dashboard shows three summary cards. The first card displays 7 as the number of enrolled students, and the second card displays 0 as the total number of female students. A third card, labelled "New employees this month", displays 385. These cards give the administrator the overall student strength in a single view.

Output 2: Dashboard1

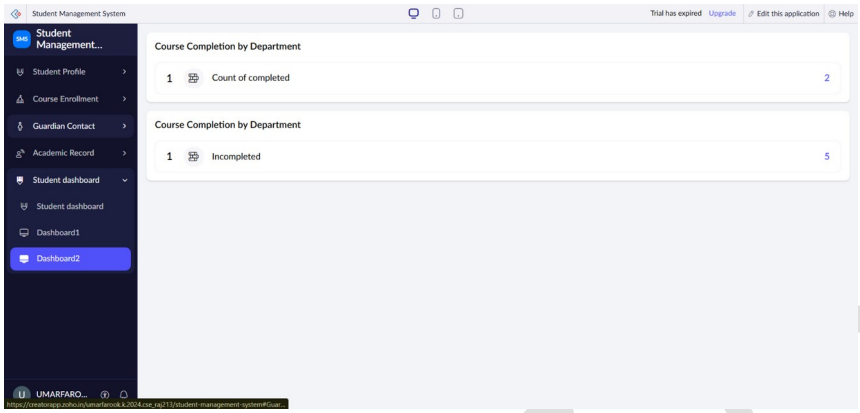

A dashboard component can be restricted with a criteria so that it counts only the records that match a given condition. In this dashboard a criteria on the gender field is applied, so the card counts only the male students instead of all the students.

Dashboard1 displays the Male Count as 7. Since the number of enrolled students is also 7 and the number of female students is 0, the figures of the two dashboards are consistent with each other, which confirms that the criteria are working correctly.

Output 3: Dashboard2

Dashboards are also used to track the status of a process. Here the course status of the students is grouped and counted, which helps the administrators to see how many students have completed their courses and how many have not, without opening the individual academic records.

Dashboard2 shows two components titled Course Completion by Department. The count of completed courses is 2 and the count of incompleted courses is 5. Together they give 7, which is equal to the number of enrolled students, so every student is accounted for in the completion summary.

RESULT:

Thus, the dashboards for the Student Management System were successfully created in Zoho Creator, and the enrolled student count, gender-wise count and course completion summary were displayed and verified.
